

# Misspecification Demonstration

Chris Legault

2022-08-16

## Overview

This demonstration explores a single realization of catch misspecification with different levels of state-space models applied to the misspecified data. The goal is to demonstrate the diagnostics that can detect the misspecification and/or account for the problem. For comparison, a correctly specified model is also shown.

## Building the data sets

The process starts with creating an initial data set using the `make_basic_info` function and assigning values for selectivity, natural mortality, and recruitment. For this example, there is a single fleet and two indices all with logistic selectivity, natural mortality is constant at 0.2 for all years and ages, and there is no stock-recruitment relationship (recruitment varies as an identical and independent deviation about the mean). The `prepare_wham_input` function creates the correctly specified input formulation.

```
# only doing one simulation here, but keep structure for multiple sims for use later
nsim <- 1

# create input
groundfish_info <- make_basic_info()

gf_selectivity = list(
  model = c(rep("logistic", groundfish_info$n_fleets), rep("logistic", groundfish_info$n_indices)),
  initial_pars = rep(list(c(5,1)), groundfish_info$n_fleets + groundfish_info$n_indices)) #fleet, index

gf_M = list(initial_means = rep(0.2, length(groundfish_info$ages)))

gf_NAA_re = list(
  Nl_pars = exp(10)*exp(-(0:(length(groundfish_info$ages)-1))*gf_M$initial_means[1]),
  sigma = "rec", #random about mean
  cor="iid", #random effects are independent
  use_steepness = 0,
  recruit_model = 2, #random effects with a constant mean
  recruit_pars = exp(10)
)

input <- prepare_wham_input(basic_info = groundfish_info,
  selectivity = gf_selectivity,
  NAA_re = gf_NAA_re,
  M= gf_M)
```

```
## [1] "number of selblocks, 3, is being determined by input$data$selblock_pointer_fleets and input$data$
```

The `fit_wham` function is run without fitting the model to create the operating model.

```
# run starter input
om <- fit_wham(input, do.fit = FALSE, MakeADFun.silent = TRUE)
```

Four estimation models are created using different levels of “state-spaceness” for the population numbers at age and recruitment formulations. The first estimation model exactly matches the operating model, meaning recruitment is estimated as a random effect about a mean value as independent and identical deviates. Ages 2 and older follow the population equation just as a statistical catch-at-age model would. The second estimation model also only has random effects for recruitment, but in this case the deviations are estimated as an autoregressive process over time. The third estimation model allows for random effects in both recruitment and for all other ages. This is the first full state-space model in the series. The random effects are all treated as independent and identical deviates with two separate sigmas estimated, one for recruitment and the other for all other ages. The fourth estimation model is also a full state-space model but the random effects are modeled as a two dimensional autoregressive process over both ages and years, with recruitment being treated separately from all other ages.

```
# set up estimation models
em_input1 <- input

gf_NAA_re2 <- gf_NAA_re
gf_NAA_re2$cor <- "ar1_y"
em_input2 <- prepare_wham_input(basic_info = groundfish_info,
                                selectivity = gf_selectivity,
                                NAA_re = gf_NAA_re2,
                                M= gf_M)
```

```
## [1] "number of selblocks, 3, is being determined by input$data$selblock_pointer_fleets and input$data$"
```

```
gf_NAA_re3 <- gf_NAA_re
gf_NAA_re3$sigma <- "rec+1"
em_input3 <- prepare_wham_input(basic_info = groundfish_info,
                                selectivity = gf_selectivity,
                                NAA_re = gf_NAA_re3,
                                M= gf_M)
```

```
## [1] "number of selblocks, 3, is being determined by input$data$selblock_pointer_fleets and input$data$"
```

```
gf_NAA_re4 <- gf_NAA_re
gf_NAA_re4$cor <- "2dar1"
gf_NAA_re4$sigma <- "rec+1"
em_input4 <- prepare_wham_input(basic_info = groundfish_info,
                                selectivity = gf_selectivity,
                                NAA_re = gf_NAA_re4,
                                M= gf_M)
```

```
## [1] "number of selblocks, 3, is being determined by input$data$selblock_pointer_fleets and input$data$"
```

Simulated data are created under two conditions: correctly and incorrectly reported catch in the recent years of the assessment. The incorrectly reported catch uses the `bias_data` function. In this example, catch is under-reported, the catch provided to the wham model is only one third of the actual catch for the second

half of the assessment time period. The four estimation models are then set up to be applied to the two sets of data, resulting in a total of 8 models. The first four `sim_inputs` use the correct catch data while the last four `sim_inputs` use the under-reported catch data.

```
#simulate data from operating model
#all RE and data are simulated
sim_input <- list()

obs_names = c("agg_indices", "agg_catch", "catch_paa", "index_paa", "Ecov_obs", "obsvec", "agesvec")

# sim_input[[1]] has no data modification and em1
set.seed(14159265) #use same seed for all operating models
sim_input[[1]] = lapply(1:nsim, function(x) {
  input_i = em_input1
  sim = om$simulate(complete=TRUE)
  input_i$data[obs_names] = sim[obs_names]
  input_i$data$obs$val = input_i$data$obsvec
  return(input_i)
})

# sim_input[[2]] uses the correct data and em2
sim_input[[2]] = lapply(1:nsim, function(x) {
  input_i = em_input2
  input_i$data[obs_names] = sim_input[[1]][[x]]$data[obs_names]
  input_i$data$obs$val = input_i$data$obsvec
  return(input_i)
})

# sim_input[[3]] uses the correct data and em3
sim_input[[3]] = lapply(1:nsim, function(x) {
  input_i = em_input3
  input_i$data[obs_names] = sim_input[[1]][[x]]$data[obs_names]
  input_i$data$obs$val = input_i$data$obsvec
  return(input_i)
})

# sim_input[[4]] uses the correct data and em4
sim_input[[4]] = lapply(1:nsim, function(x) {
  input_i = em_input4
  input_i$data[obs_names] = sim_input[[1]][[x]]$data[obs_names]
  input_i$data$obs$val = input_i$data$obsvec
  return(input_i)
})

# now create the under-reported catch data
# sim_input[[5]] has under-reported catch and em1
set.seed(14159265) #use same seed for all operating models
agg_catch_multiplier <- create_agg_catch_multiplier(input, multiplier=0.33)
sim_input[[5]] = lapply(1:nsim, function(x) {
  input_i = em_input1
  sim = om$simulate(complete=TRUE)
  sim <- bias_data(sim, multiply_agg_catch_flag=TRUE,
                   agg_catch_multiplier=agg_catch_multiplier)
  input_i$data[obs_names] = sim[obs_names]
})
```

```

    input_i$data$obs$val = input_i$data$obsvec
    return(input_i)
  })

  # sim_input[[6]] has under-reported catch and em2
  sim_input[[6]] = lapply(1:nsim, function(x) {
    input_i = em_input2
    input_i$data[obs_names] = sim_input[[5]][[x]]$data[obs_names]
    input_i$data$obs$val = input_i$data$obsvec
    return(input_i)
  })

  # sim_input[[7]] has under-reported catch and em3
  sim_input[[7]] = lapply(1:nsim, function(x) {
    input_i = em_input3
    input_i$data[obs_names] = sim_input[[5]][[x]]$data[obs_names]
    input_i$data$obs$val = input_i$data$obsvec
    return(input_i)
  })

  # sim_input[[8]] has under-reported catch and em4
  sim_input[[8]] = lapply(1:nsim, function(x) {
    input_i = em_input4
    input_i$data[obs_names] = sim_input[[5]][[x]]$data[obs_names]
    input_i$data$obs$val = input_i$data$obsvec
    return(input_i)
  })

```

Check to see that the eight data sets have the correct aggregate catch. Models 1-4 have the true catch, while models 5-8 have the under-reported catch in recent years.

```

aggc <- tibble(Model = character(), Year = integer(), AggCatch = double())
for (m in 1:8){
  aggcdat <- lapply(1:nsim, function(x){
    out <- sim_input[[m]][[x]]$data$agg_catch
    return(out)
  })
  thisaggc <- tibble(Model = m,
                    Year = 1:sim_input[[m]][[1]]$data$n_years_model,
                    AggCatch = unlist(aggcdat))
  aggc <- rbind(aggc, thisaggc)
}

p1 <- ggplot(aggc, aes(x=Year, y=AggCatch)) +
  geom_point() +
  geom_line() +
  facet_wrap(~Model, ncol = 4) +
  expand_limits(y = 0) +
  theme_bw()

print(p1)

```

## Run the models

Now run the eight models. This may take a few minutes. The Rmarkdown compilation checks to see if the file `misspec_demo_fits.RDS` is present in the `misspecification_study` directory. If it is, it simply reads that file. If it is not, then the model is run. So if you change any of the settings above, be sure to remove the RDS file before knitting the Rmarkdown script. This RDS file is relatively large (~16 MB), so is not saved on the GitHub repo.

```
if(file.exists(file.path(here(), "misspecification_study", "misspec_demo_fits.RDS"))){
  em_fits <- readRDS(file.path(here(), "misspecification_study", "misspec_demo_fits.RDS"))
} else {
  # run the models
  em_fits = list()
  for(m in 1:8){
    em_fits[[m]] = lapply(1:nsim, function(x){
      out = fit_wham(sim_input[[m]][[x]],
        do.osa = TRUE,
        MakeADFun.silent = TRUE,
        retro.silent = TRUE,
        save.sdrep = TRUE)

      return(out)
    })
  }
  saveRDS(em_fits, file.path(here(), "misspecification_study", "misspec_demo_fits.RDS"))
}
```

Start by making sure all the models converged. Model 4 (correct data with estimation model 4) did not converge. Kept in for now just for completeness, but this is a good reminder to make sure the model converges before digging into the results.

```
check_convergence(em_fits[[1]][[1]])
```

```
## stats:nlminb thinks the model has converged: mod$opt$convergence == 0
## Maximum gradient component: 1.20e-12
## Max gradient parameter: logit_selpars
## TMB:sdreport() was performed successfully for this model
```

```
check_convergence(em_fits[[2]][[1]])
```

```

```

## Correct data results

We can see which model has the best fit using the `compare_wham_models` function for the two sets of data. Start with the correctly reported catch data (CD). We see all four estimation models (em) fit the data similarly for F, recruitment, and SSB, with similar CVs for each. Estimation model 2 (AR1 random walk in recruitment) was preferred over the other three estimation models, but the differences in AIC were not great (<5 units). Mohn's rho for SSB and F and were low for all four estimation models (absolute values < 0.6).

```
# don't know why this code is not working anymore
# correct_data_compare <- compare_wham_models(list(CD_em1 = em_fits[[1]][[1]],
#                                                    CD_em2 = em_fits[[2]][[1]],
#                                                    CD_em3 = em_fits[[3]][[1]],
#                                                    CD_em4 = em_fits[[4]][[1]]))
#
# print(correct_data_compare$g[[1]])
# print(correct_data_compare$g[[2]])
#      dAIC    AIC  rho_R rho_SSB rho_Fbar
# CD_em2  0.0 5008.4 0.2629 -0.0418  0.0573
# CD_em1  2.4 5010.8 0.3136 -0.0285  0.0416
# CD_em4  3.9 5012.3 0.2772 -0.0340  0.0506
# CD_em3  4.4 5012.8 0.3136 -0.0285  0.0416
# Error in if (is.na(rel.f.vals[x]) | any(diag(log.rel.ssb.rel.F.cov[[x]]) < :
#   missing value where TRUE/FALSE needed
```

## Under-reported catch data results

The under-reported catch data (UR) found greater differences among the four models. Estimation model 4 (full state-space with 2dar1 correlations) was the preferred model based on AIC, with the other models >50 units worse. The Mohn's rho values for SSB and F for estimation model 4 were lower than all the values from the correct data, while the other three estimation models were all worse (absolute values >0.20). So according to both AIC and the retrospective diagnostic, estimation model 4 is highly preferred to the other three estimation models for the under-reported catch data. All four estimation models show a spike in F in year 2000, just before the catch under-reporting begins. The big difference is in the scale of the F, recruitment, and SSB point estimates, with estimation model 4 showing lower F and higher recruitment and SSB than the other three estimation models. The trends in F, recruitment, and SSB are similar though. The uncertainty of estimation model 4 is much higher than the other three models. It is not clear what is driving the large uncertainty in estimation model 4 (Tim - do you have any thoughts?).

```
misspecified_data_compare <- compare_wham_models(list(UR_em1 = em_fits[[5]][[1]],
                                                    UR_em2 = em_fits[[6]][[1]],
                                                    UR_em3 = em_fits[[7]][[1]],
                                                    UR_em4 = em_fits[[8]][[1]]))
```

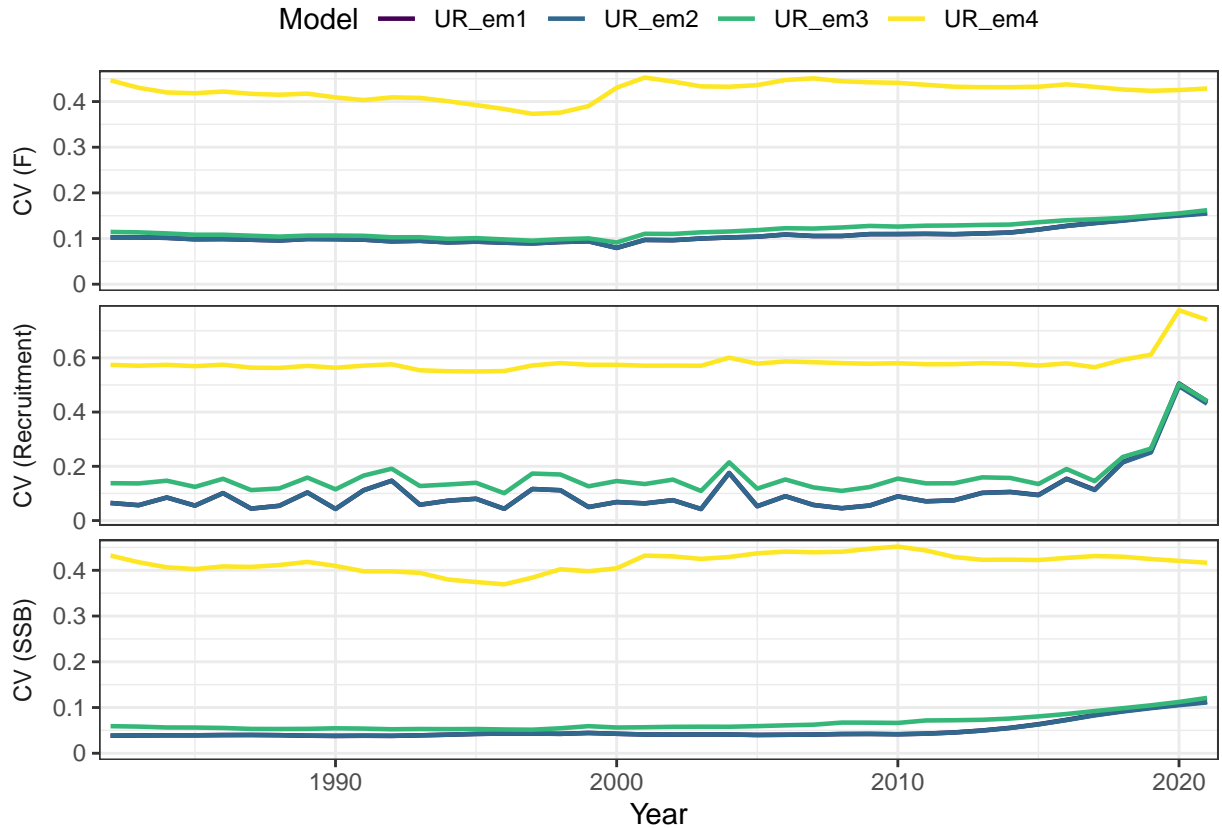

```
##      dAIC      AIC rho_R rho_SSB rho_Fbar
## UR_em4  0.0 5102.0 0.4805  0.0275 -0.0149
## UR_em3 58.9 5160.9 0.5167  0.2771 -0.2377
## UR_em1 68.4 5170.4 0.5224  0.2981 -0.2609
## UR_em2 68.7 5170.7 0.4851  0.2884 -0.2550
```

```
print(misspecified_data_compare$g[[1]])
```

```
print(misspecified_data_compare$g[[2]])
```

Looking at the fits to the under-reported data for estimation model 4 (using `plot_wham_output(mod=em_fits[[8]][[1]], out.type='html')`), I was surprised by how well most things fit, with no obvious patterning in residuals or obvious misfits. The one bad diagnostic I saw was the conditional expected and posterior estimates of abundance at all ages where the line was above all the points for all years and ages. So there was one diagnostic that indicated that there is a model misfit, but not anything that jumped out at me from the tabular data that could easily be grabbed when running lots of realizations.

```
# ran into errors plotting the one-step-ahead residuals for each model
# ran the loop one model at a time to get output
#
# em_fits 1 and 5 gave error message
# Error in mod$osa[c(dat$keep_Cpaa[i, yind, ] + 1), ] :
#   incorrect number of dimensions
#
# the other six em_fits gave error message
# Infinite osa residuals for aggregate catch in fleet 1 , so using +/-10 for range of y axis
# Error in if (h > 0) max(1, ceiling(diff(range(x))/h)) else 1L :
#   missing value where TRUE/FALSE needed
# In addition: Warning messages:
# 1: In min(x) : no non-missing arguments to min; returning Inf
# 2: In max(x) : no non-missing arguments to max; returning -Inf

# can either pull this code out and run in console, or else uncomment and knit then comment and knit ag
out.dir <- file.path(here(), "misspecification_study", "output")
if (!dir.exists(out.dir)){
  dir.create(out.dir)
```

```

}
mydir <- c(paste0("CC_em", 1:4), paste0("UR_em", 1:4))
for (i in 1:8){
  em.dir <- file.path(here(), "misspecification_study", "output", mydir[i])
  if(!dir.exists(em.dir)){
    dir.create(em.dir)
  }
  plot_wham_output(mod=em_fits[[i]][[1]], dir.main=em.dir)
}

```

The catch and index four panel plots all look good for UR\_em4. The problematic diagnostic is the NAA 4 panel plots, show below for ages 1 and 8 as well as the stacked barplot of residuals. Also, none of the one-step-ahead residual plots are currently working. Tim is looking into this, could be a non-trivial fix is required.

Use Liz's plot.retro.pars function to examine the stability of parameter estimates across the retrospective peels. For now just look at under-reported catch case with estimation model 4 (UR\_em4).

```

# again had to run this in console because could not get it to knit
# for (i in 1:8){
#   emlr.dir <- file.path(here(), "misspecification_study", "output", mydir[i], "liz_retro_plots")
#   if(!dir.exists(emlr.dir)){
#     dir.create(emlr.dir)
#   }
#   plot.retro.pars(m=em_fits[[i]][[1]], yr.plot.start=2005, od=emlr.dir, save.name=mydir[i],
#                   plot.f='png' )
# }

```

None of the retrospective plots show a strong pattern. The unusual result of nearly all the NAA log\_Deviations being below zero holds for all the peels.

Interestingly, for estimation model 3, both the fits and the NAA log deviations showed a strong pattern of positive then negative or else negative then positive residuals over time.
